

Go Planning

This document outlines the algorithm and user instructions for a simplified 9x9 Go board game program. The program allows two players (Black and White) to alternately place stones on the board until the user decides to stop.

Algorithm

- Initialize an empty 9x9 board using a list of lists. Each position starts as a period ('.') representing an empty point.
- Set the current player to Black (Black always moves first).
- Display the current board state to the user.
- Prompt the user for input: either a coordinate (e.g., 'C5') where they want to place their stone, or 'stop' to end the game.
- If the user enters 'stop', end the game loop and display a closing message.
- Translate the coordinate input into board indices.
- Check if the chosen position is empty:
 - If empty: Place the stone ('B' for Black, 'W' for White) at the position
 - If not empty: Print an error message and ask the user to try again.
 - After a successful move, alternate turns between players.

Prompt user again and repeat until the user enters 'stop'.

User Instructions

The board is labeled with coordinates similar to a chessboard system:

Columns are labeled A through I.

Rows are labeled 1 through 9.

For example, 'C5' refers to column C, row 5.

Players take turns placing stones, starting with Black.

To place a stone, type the coordinate (e.g., 'E7') and press Enter.

To stop the game at any time, type 'stop' and press Enter.

If you try to place a stone on an occupied point, the program will reject the move and prompt you again.

The board will be displayed after every valid move
